Destructuring assignment

The two most used data structures in JavaScript are `Object` and `Array`.

Objects allow us to create a single entity that stores data items by key, and arrays allow us to gather data items into an ordered collection.

But when we pass those to a function, it may need not an object/array as a whole, but rather individual pieces.

Destructuring assignment is a special syntax that allows us to “unpack” arrays or objects into a bunch of variables, as sometimes that’s more convenient. Destructuring also works great with complex functions that have a lot of parameters, default values, and so on.

Array destructuring

An example of how the array is destructured into variables:

```
1 // we have an array with the name and surname
2 let arr = ["Ilya", "Kantor"]
3
4 // destructuring assignment
5 // sets firstName = arr[0]
6 // and surname = arr[1]
7 let [firstName, surname] = arr;
8
9 alert(firstName); // Ilya
10 alert(surname); // Kantor
```

Now we can work with variables instead of array members.

It looks great when combined with `split` or other array-returning methods:

```
1 let [firstName, surname] = "Ilya Kantor".split(' ');
```

i “Destructuring” does not mean “destructive”.

It's called “destructuring assignment,” because it “deconstructs” by copying items into variables. But the array itself is not modified.

It's just a shorter way to write:

```
1 // let [firstName, surname] = arr;
2 let firstName = arr[0];
3 let surname = arr[1];
```

i Ignore elements using commas

Unwanted elements of the array can also be thrown away via an extra comma:

```
1 // second element is not needed
2 let [firstName, , title] = ["Julius", "Caesar", "Consul", "of the Roman Re
3
4 alert( title ); // Consul
```

In the code above, the second element of the array is skipped, the third one is assigned to `title`, and the rest of the array items is also skipped (as there are no variables for them).

i Works with any iterable on the right-side

...Actually, we can use it with any iterable, not only arrays:

```
1 let [a, b, c] = "abc"; // ["a", "b", "c"]
2 let [one, two, three] = new Set([1, 2, 3]);
```

i Assign to anything at the left-side

We can use any “assignables” at the left side.

For instance, an object property:

```
1 let user = {};
2 [user.name, user.surname] = "Ilya Kantor".split(' ');
3
4 alert(user.name); // Ilya
```

Looping with .entries()

In the previous chapter we saw the `Object.entries(obj)` method.

We can use it with destructuring to loop over keys-and-values of an object:

```
1 let user = {  
2   name: "John",  
3   age: 30  
4 };  
5  
6 // loop over keys-and-values  
7 for (let [key, value] of Object.entries(user)) {  
8   alert(`${key}:${value}`); // name:John, then age:30  
9 }
```

...And the same for a map:

```
1 let user = new Map();  
2 user.set("name", "John");  
3 user.set("age", "30");  
4  
5 for (let [key, value] of user) {  
6   alert(`${key}:${value}`); // name:John, then age:30  
7 }
```

The rest '...'

If we want not just to get first values, but also to gather all that follows – we can add one more parameter that gets “the rest” using three dots "...":

```
1 let [name1, name2, ...rest] = ["Julius", "Caesar", "Consul", "of the Roman Re  
2  
3 alert(name1); // Julius  
4 alert(name2); // Caesar  
5  
6 // Note that type of `rest` is Array.  
7 alert(rest[0]); // Consul  
8 alert(rest[1]); // of the Roman Republic  
9 alert(rest.length); // 2
```

The value of `rest` is the array of the remaining array elements. We can use any other variable name in place of `rest`, just make sure it has three dots before it and goes last in the destructuring assignment.

Default values

If there are fewer values in the array than variables in the assignment, there will be no error. Absent values are considered undefined:

```
1 let [firstName, surname] = [];  
2  
3 alert(firstName); // undefined  
4 alert(surname); // undefined
```

If we want a “default” value to replace the missing one, we can provide it using `=`:

```
1 // default values  
2 let [name = "Guest", surname = "Anonymous"] = ["Julius"];  
3  
4 alert(name); // Julius (from array)  
5 alert(surname); // Anonymous (default used)
```

Default values can be more complex expressions or even function calls. They are evaluated only if the value is not provided.

For instance, here we use the `prompt` function for two defaults. But it will run only for the missing one:

```
1 // runs only prompt for surname  
2 let [name = prompt('name?'), surname = prompt('surname?')] = ["Julius"];  
3  
4 alert(name); // Julius (from array)  
5 alert(surname); // whatever prompt gets
```

Object destructuring

The destructuring assignment also works with objects.

The basic syntax is:

```
1 let {var1, var2} = {var1:..., var2:...}
```

We have an existing object at the right side, that we want to split into variables. The left side contains a “pattern” for corresponding properties. In the simple case, that’s a list of variable names in `{...}`.

For instance:

```
1 let options = {  
2   title: "Menu",  
3   width: 100,  
4   height: 200  
5 };  
6  
7 let {title, width, height} = options;  
8  
9 alert(title); // Menu  
10 alert(width); // 100  
11 alert(height); // 200
```

Properties `options.title`, `options.width` and `options.height` are assigned to the corresponding variables. The order does not matter. This works too:

```
1 // changed the order in let {...}
2 let {height, width, title} = { title: "Menu", height: 200, width: 100 }
```

The pattern on the left side may be more complex and specify the mapping between properties and variables.

If we want to assign a property to a variable with another name, for instance, `options.width` to go into the variable named `w`, then we can set it using a colon:

```
1 let options = {
2   title: "Menu",
3   width: 100,
4   height: 200
5 };
6
7 // { sourceProperty: targetVariable }
8 let {width: w, height: h, title} = options;
9
10 // width -> w
11 // height -> h
12 // title -> title
13
14 alert(title); // Menu
15 alert(w);     // 100
16 alert(h);     // 200
```

The colon shows “what : goes where”. In the example above the property `width` goes to `w`, property `height` goes to `h`, and `title` is assigned to the same name.

For potentially missing properties we can set default values using `"="`, like this:

```
1 let options = {
2   title: "Menu"
3 };
4
5 let {width = 100, height = 200, title} = options;
6
7 alert(title); // Menu
8 alert(width); // 100
9 alert(height); // 200
```

Just like with arrays or function parameters, default values can be any expressions or even function calls. They will be evaluated if the value is not provided.

In the code below `prompt` asks for `width`, but not for `title`:

```
1 let options = {
2   title: "Menu"
3 };
4
```

```
5 let {width = prompt("width?"), title = prompt("title?")} = options;
6
7 alert(title); // Menu
8 alert(width); // (whatever the result of prompt is)
```

We also can combine both the colon and equality:

```
1 let options = {
2   title: "Menu"
3 };
4
5 let {width: w = 100, height: h = 200, title} = options;
6
7 alert(title); // Menu
8 alert(w);      // 100
9 alert(h);      // 200
```

If we have a complex object with many properties, we can extract only what we need:

```
1 let options = {
2   title: "Menu",
3   width: 100,
4   height: 200
5 };
6
7 // only extract title as a variable
8 let { title } = options;
9
10 alert(title); // Menu
```

The rest pattern “...”

What if the object has more properties than we have variables? Can we take some and then assign the “rest” somewhere?

We can use the rest pattern, just like we did with arrays. It's not supported by some older browsers (IE, use Babel to polyfill it), but works in modern ones.

It looks like this:

```
1 let options = {
2   title: "Menu",
3   height: 200,
4   width: 100
5 };
6
7 // title = property named title
8 // rest = object with the rest of properties
9 let {title, ...rest} = options;
10
11 // now title="Menu", rest={height: 200, width: 100}
12 alert(rest.height); // 200
13 alert(rest.width);  // 100
```

Gotcha if there's no `let`

In the examples above variables were declared right in the assignment: `let {...} = {...}`. Of course, we could use existing variables too, without `let`. But there's a catch.

This won't work:

```
1 let title, width, height;
2
3 // error in this line
4 {title, width, height} = {title: "Menu", width: 200, height: 100};
```

The problem is that JavaScript treats `{...}` in the main code flow (not inside another expression) as a code block. Such code blocks can be used to group statements, like this:

```
1 {
2   // a code block
3   let message = "Hello";
4   // ...
5   alert( message );
6 }
```

So here JavaScript assumes that we have a code block, that's why there's an error. We want destructuring instead.

To show JavaScript that it's not a code block, we can wrap the expression in parentheses `(...)`:

```
1 let title, width, height;
2
3 // okay now
4 ({title, width, height} = {title: "Menu", width: 200, height: 100});
5
6 alert( title ); // Menu
```

Nested destructuring

If an object or an array contain other nested objects and arrays, we can use more complex left-side patterns to extract deeper portions.

In the code below `options` has another object in the property `size` and an array in the property `items`. The pattern at the left side of the assignment has the same structure to extract values from them:

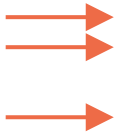

```
1 let options = {
2   size: {
3     width: 100,
4     height: 200
5   },
```

```

6   items: ["Cake", "Donut"],
7   extra: true
8 };
9
10 // destructuring assignment split in multiple lines for clarity
11 let {
12     size: { // put size here
13         width,
14         height
15     },
16     items: [item1, item2], // assign items here
17     title = "Menu" // not present in the object (default value is used)
18 } = options;
19
20 alert(title); // Menu
21 alert(width); // 100
22 alert(height); // 200
23 alert(item1); // Cake
24 alert(item2); // Donut

```

All properties of `options` object except `extra` that is absent in the left part, are assigned to corresponding variables:

<pre> let { size: { width, height }, items: [item1, item2], title = "Menu" } </pre>		<pre> let options = { size: { width: 100, height: 200 }, items: ["Cake", "Donut"], extra: true } </pre>
---	--	---

Finally, we have `width`, `height`, `item1`, `item2` and `title` from the default value.

Note that there are no variables for `size` and `items`, as we take their content instead.

Smart function parameters

There are times when a function has many parameters, most of which are optional. That's especially true for user interfaces. Imagine a function that creates a menu. It may have a width, a height, a title, items list and so on.

Here's a bad way to write such function:

```

1 function showMenu(title = "Untitled", width = 200, height = 100, items = [])
2   // ...
3 }

```

In real-life, the problem is how to remember the order of arguments. Usually IDEs try to help us, especially if the code is well-documented, but still... Another problem is how to call a function when most parameters are ok by default.

Like this?

```

1 // undefined where default values are fine
2 showMenu("My Menu", undefined, undefined, ["Item1", "Item2"])

```

That's ugly. And becomes unreadable when we deal with more parameters.

Destructuring comes to the rescue!

We can pass parameters as an object, and the function immediately deconstructurizes them into variables:

```

1 // we pass object to function
2 let options = {
3   title: "My menu",
4   items: ["Item1", "Item2"]
5 };
6
7 // ...and it immediately expands it to variables
8 function showMenu({title = "Untitled", width = 200, height = 100, items = []})
9   // title, items – taken from options,
10  // width, height – defaults used
11  alert( `${title} ${width} ${height}` ); // My Menu 200 100
12  alert( items ); // Item1, Item2
13 }
14
15 showMenu(options);

```

We can also use more complex destructuring with nested objects and colon mappings:

```

1 let options = {
2   title: "My menu",
3   items: ["Item1", "Item2"]
4 };
5
6 function showMenu({
7   title = "Untitled",
8   width: w = 100, // width goes to w
9   height: h = 200, // height goes to h
10  items: [item1, item2] // items first element goes to item1, second to item2
11 }) {
12  alert( `${title} ${w} ${h}` ); // My Menu 100 200
13  alert( item1 ); // Item1
14  alert( item2 ); // Item2
15 }
16
17 showMenu(options);

```

The full syntax is the same as for a destructuring assignment:

```

1 function({
2   incomingProperty: varName = defaultValue
3   ...
4 })

```

Then, for an object of parameters, there will be a variable `varName` for property `incomingProperty`, with `defaultValue` by default.

Please note that such destructuring assumes that `showMenu()` does have an argument. If we want all values by default, then we should specify an empty object:

```
1 showMenu({}); // ok, all values are default
2
3 showMenu(); // this would give an error
```

We can fix this by making `{}` the default value for the whole object of parameters:

```
1 function showMenu({ title = "Menu", width = 100, height = 200 } = {}) {
2   alert( `${title} ${width} ${height}` );
3 }
4
5 showMenu(); // Menu 100 200
```

In the code above, the whole arguments object is `{}` by default, so there's always something to destructure.

Summary

- Destructuring assignment allows for instantly mapping an object or array onto many variables.
- The full object syntax:

```
1 let {prop : varName = default, ...rest} = object
```

This means that property `prop` should go into the variable `varName` and, if no such property exists, then the `default` value should be used.

Object properties that have no mapping are copied to the `rest` object.

- The full array syntax:

```
1 let [item1 = default, item2, ...rest] = array
```

The first item goes to `item1`; the second goes into `item2`, all the rest makes the array `rest`.

- It's possible to extract data from nested arrays/objects, for that the left side must have the same structure as the right one.

✓ Tasks

Destructuring assignment [↗](#)

importance: 5

We have an object:

```
1 let user = {  
2   name: "John",  
3   years: 30  
4 };
```

Write the destructuring assignment that reads:

- `name` property into the variable `name` .
- `years` property into the variable `age` .
- `isAdmin` property into the variable `isAdmin` (false, if no such property)

Here's an example of the values after your assignment:

```
1 let user = { name: "John", years: 30 };  
2  
3 // your code to the left side:  
4 // ... = user  
5  
6 alert( name ); // John  
7 alert( age ); // 30  
8 alert( isAdmin ); // false
```

solution

The maximal salary

importance: 5

There is a `salaries` object:

```
1 let salaries = {  
2   "John": 100,  
3   "Pete": 300,  
4   "Mary": 250  
5 };
```

Create the function `topSalary(salaries)` that returns the name of the top-paid person.

- If `salaries` is empty, it should return `null` .
- If there are multiple top-paid persons, return any of them.

P.S. Use `Object.entries` and destructuring to iterate over key/value pairs.
